FEEDBACK REPORT

Technical Programming SLP | 26–30 October 2026

DAY 01 — 2026.10.26

First steps in Level 3 C++

We began by discussing the course content and the practical skills expected in Level 3. The early work stressed the need to read a programming problem carefully and decide on a solution before starting to type. I also became more aware of the importance of organising project files.

The C++ development process and GitHub formed part of the introduction. I found the idea of saving each working stage useful. It gives both the lecturer and learner a way to see how a program has grown and where a problem may have started.

DAY 02 — 2026.10.27

Numbers, input and presentation

The day's lessons covered data types, variables, constants and arithmetic. We checked how the order of operations affects calculations and how output can be displayed to a set number of decimal places. The difference between integer and decimal division stood out to me.

We used a water-tank problem to apply the work. After drawing the plan, we used maths functions and checked for invalid input. I learned to test the program with different values rather than assuming that one correct result means the whole program works.

DAY 03 — 2026.10.28

Control structures in practice

The third day brought together conditions, loops and a menu. We explored how the program should respond to a user's choice and how to keep asking for a valid mark. The statistics task calculated totals, averages, highest and lowest marks.

The debugging session made me think about errors in a different way. A program may run but still produce the wrong result. We had to examine starting values, ranges and what happens when no marks have been entered. These are checks I want learners to include in their own tests.

DAY 04 — 2026.10.29

Functions, arrays and strings

We learned how to divide a program into functions. The work covered prototypes, parameters, return values and scope. I found it easier to understand the program when each function was responsible for one task.

We also worked with one-dimensional arrays and strings. The exercises showed how to process a group of values and compare text. My reflection is that learners should first understand the small pieces, then combine them into a program that solves a bigger problem.

DAY 05 — 2026.10.30

Building a product-based application

Friday introduced object-oriented programming. We examined classes, objects, constructors and the use of private attributes with public methods. A product in a spaza shop was used to show how these ideas work in a real situation.

The afternoon task was a till program with products, quantities and totals. We considered searching for product codes, validating entries and testing the result. The week ended with project review and evidence of practical work. I can use this example to show learners how several C++ topics work together.
